

Vapnik–Chervonenkis classes

Maxim Raginsky

October 1, 2013

A key result on the ERM algorithm, proved in the previous lecture, was that

$$P(\hat{f}_n) \leq L^*(\mathcal{F}) + 4\mathbb{E}R_n(\mathcal{F}(Z^n)) + \sqrt{\frac{2\log(1/\delta)}{n}}$$

with probability at least $1 - \delta$. The quantity $R_n(\mathcal{F}(Z^n))$ appearing on the right-hand side of the above bound is the *Rademacher average* of the random set

$$\mathcal{F}(Z^n) = \{(f(Z_1), \dots, f(Z_n)) : f \in \mathcal{F}\},$$

often referred to as the *projection* of \mathcal{F} onto the sample Z^n . From this we see that a sufficient condition for the ERM algorithm to produce near-optimal hypotheses with high probability is that the expected Rademacher average $\mathbb{E}R_n(\mathcal{F}(Z^n)) = \tilde{O}(1/\sqrt{n})$, where the $\tilde{O}(\cdot)$ notation indicates that the bound holds up to polylogarithmic factors in n , i.e., there exists some positive polynomial function $p(\cdot)$ such that

$$\mathbb{E}R_n(\mathcal{F}(Z^n)) \leq O\left(\sqrt{\frac{p(\log n)}{n}}\right).$$

Hence, a lot of effort in statistical learning theory is devoted to obtaining tight bounds on $\mathbb{E}R_n(\mathcal{F}(Z^n))$.

One way to guarantee an $\tilde{O}(1/\sqrt{n})$ bound on $\mathbb{E}R_n$ is if the “effective size” of the random set $\mathcal{F}(Z^n)$ is finite and grows polynomially with n . Then the Finite Class Lemma will tell us that

$$R_n(\mathcal{F}(Z^n)) = O\left(\sqrt{\frac{\log n}{n}}\right).$$

In general, a reasonable notion of “effective size” is captured by various *covering numbers* (see, e.g., the lecture notes by Mendelson [Men03] or the recent monograph by Talagrand [Tal05] for detailed expositions of the relevant theory). In this lecture, we will look at a simple combinatorial notion of effective size for classes of *binary-valued* functions. This particular notion has originated with the work of Vapnik and Chervonenkis [VC71], and was historically the first such notion to be introduced into statistical learning theory. It is now known as the *Vapnik–Chervonenkis* (or *VC*) *dimension*.

1 Vapnik–Chervonenkis dimension: definition

Definition 1. Let \mathcal{C} be a class of (measurable) subsets of some space Z . We say that a finite set $S = \{z_1, \dots, z_n\} \subset Z$ is shattered by \mathcal{C} if for every subset $S' \subseteq S$ there exists some $C \in \mathcal{C}$ such that $S' = S \cap C$.

In other words, $S = \{z_1, \dots, z_n\}$ is shattered by \mathcal{C} if for any binary n -tuple $b = (b_1, \dots, b_n) \in \{0, 1\}^n$ there exists some $C \in \mathcal{C}$ such that

$$(\mathbf{1}_{\{z_1 \in C\}}, \dots, \mathbf{1}_{\{z_n \in C\}}) = b$$

or, equivalently, if

$$\{(\mathbf{1}_{\{z_1 \in C\}}, \dots, \mathbf{1}_{\{z_n \in C\}}) : C \in \mathcal{C}\} = \{0, 1\}^n,$$

where we consider any two $C_1, C_2 \in \mathcal{C}$ as equivalent if $\mathbf{1}_{\{z_i \in C_1\}} = \mathbf{1}_{\{z_i \in C_2\}}$ for all $1 \leq i \leq n$.

Definition 2. The Vapnik–Chervonenkis dimension (or the VC dimension) of \mathcal{C} is

$$V(\mathcal{C}) \triangleq \max \left\{ n \in \mathbb{N} : \exists S \subset Z \text{ such that } |S| = n \text{ and } S \text{ is shattered by } \mathcal{C} \right\}.$$

If $V(\mathcal{C}) < \infty$, we say that \mathcal{C} is a VC class (of sets).

We can express the VC dimension in terms of *shatter coefficients* of \mathcal{C} : Let

$$\mathbb{S}_n(\mathcal{C}) \triangleq \sup_{S \subset Z, |S|=n} |\{S \cap C : C \in \mathcal{C}\}|$$

denote the n th *shatter coefficient* of \mathcal{C} , where for each fixed S we consider any two $C_1, C_2 \in \mathcal{C}$ as equivalent if $S \cap C_1 = S \cap C_2$. Then

$$V(\mathcal{C}) = \max \left\{ n \in \mathbb{N} : \mathbb{S}_n(\mathcal{C}) = 2^n \right\}.$$

The VC dimension $V(\mathcal{C})$ may be infinite, but it is always well-defined. This follows from the following lemma:

Lemma 1. If $\mathbb{S}_n(\mathcal{C}) < 2^n$, then $\mathbb{S}_m(\mathcal{C}) < 2^m$ for all $m > n$.

Proof. Suppose $\mathbb{S}_n(\mathcal{C}) < 2^n$. Consider any $m > n$. We will suppose that $\mathbb{S}_m(\mathcal{C}) = 2^m$ and derive a contradiction. Let us choose an arbitrary binary n -tuple $b = (b_1, \dots, b_n)$. Moreover, choose an arbitrary $S = \{z_1, \dots, z_n\} \subset Z$ and some other $T = \{z'_1, \dots, z'_{m-n}\} \subset Z$ with $S \cap T = \emptyset$. By our assumption that $\mathbb{S}_m(\mathcal{C}) = 2^m$, given

$$b' = (\underbrace{b_1, \dots, b_n}_b, \underbrace{0, \dots, 0}_{m-n \text{ times}})$$

and $S' = S \cup T = \{z_1, \dots, z_n, z'_1, \dots, z'_{m-n}\}$, we can find some $C \in \mathcal{C}$ such that

$$\left(\mathbf{1}_{\{z_1 \in C\}}, \dots, \mathbf{1}_{\{z_n \in C\}}, \mathbf{1}_{\{z'_1 \in C\}}, \dots, \mathbf{1}_{\{z'_{m-n} \in C\}} \right) = (b_1, \dots, b_n, 0, \dots, 0). \quad (1)$$

From (1) it immediately follows that

$$\left(\mathbf{1}_{\{z_1 \in C\}}, \dots, \mathbf{1}_{\{z_n \in C\}} \right) = (b_1, \dots, b_n) = b. \quad (2)$$

Since $b = (b_1, \dots, b_n)$ and $S = \{z_1, \dots, z_n\}$ were arbitrary, we see from (2) that $\mathbb{S}_n(\mathcal{C}) = 2^n$. This contradicts our assumption that $\mathbb{S}_n(\mathcal{C}) < 2^n$, so we conclude that $\mathbb{S}_m(\mathcal{C}) < 2^m$ whenever $m > n$ and $\mathbb{S}_n(\mathcal{C}) < 2^n$. \square

There is a one-to-one correspondence between binary-valued functions $f : Z \rightarrow \{0, 1\}$ and subsets of Z :

$$\begin{aligned} \forall f : Z \rightarrow \{0, 1\} \text{ let } C_f &\triangleq \{z : f(z) = 1\} \\ \forall C \subseteq Z \text{ let } f_C &\triangleq \mathbf{1}_{\{C\}}. \end{aligned}$$

Thus, we can extend the concept of shattering, as well as the definition of the VC dimension, to any class \mathcal{F} of functions $f : Z \rightarrow \{0, 1\}$:

Definition 3. Let \mathcal{F} be a class of functions $f : Z \rightarrow \{0, 1\}$. We say that a finite set $S = \{z_1, \dots, z_n\} \subset Z$ is shattered by \mathcal{F} if it is shattered by the class

$$\mathcal{C}_{\mathcal{F}} \triangleq \{\mathbf{1}_{\{f=1\}} : f \in \mathcal{F}\},$$

where $\mathbf{1}_{\{f=1\}}$ is the indicator function of the set $C_f \triangleq \{z \in Z : f(z) = 1\}$. The n th shatter coefficient of \mathcal{F} is $\mathbb{S}_n(\mathcal{F}) = \mathbb{S}_n(\mathcal{C}_{\mathcal{F}})$, and the VC dimension of \mathcal{F} is defined as $V(\mathcal{F}) = V(\mathcal{C}_{\mathcal{F}})$.

In light of these definitions, we can equivalently speak of the VC dimension of a class of sets or a class of binary-valued functions.

2 Examples of Vapnik–Chervonenkis classes

2.1 Semi-infinite intervals

Let $Z = \mathbb{R}$ and take \mathcal{C} to be the class of all intervals of the form $(-\infty, t]$ as t varies over \mathbb{R} . We will prove that $V(\mathcal{C}) = 1$. In view of Lemma 1, it suffices to show that (1) any one-point set $S = \{a\}$ is shattered by \mathcal{C} , and (2) no two-point set $S = \{a, b\}$ is shattered by \mathcal{C} .

Given $S = \{a\}$, choose any $t_1 < a$ and $t_2 > a$. Then $(-\infty, t_1] \cap S = \emptyset$ and $(-\infty, t_2] \cap S = S$. Thus, S is shattered by \mathcal{C} . This holds for every one-point set S , and therefore we have proved (1). To prove (2), let $S = \{a, b\}$ and suppose, without loss of generality, that $a < b$. Then there exists no $t \in \mathbb{R}$ such that $(-\infty, t] \cap S = \{b\}$. This follows from the fact that if $b \in (-\infty, t] \cap S$, then $t \geq b$. Since $b > a$, we must have $t > a$, so that $a \in (-\infty, t] \cap S$ as well. Since a and b are arbitrary, we see that no two-point subset of \mathbb{R} can be shattered by \mathcal{C} .

2.2 Closed intervals

Again, let $Z = \mathbb{R}$ and take \mathcal{C} to be the class of all intervals of the form $[s, t]$ for all $s, t \in \mathbb{R}$. Then $V(\mathcal{C}) = 2$. To see this, we will show that (1) any two point set $S = \{a, b\}$ can be shattered by \mathcal{C} and that (2) no three-point set $S = \{a, b, c\}$ can be shattered by \mathcal{C} .

For (1), let $S = \{a, b\}$ and suppose, without loss of generality, that $a < b$. Choose four points $t_1, t_2, t_3, t_4 \in \mathbb{R}$ such that $t_1 < t_2 < a < t_3 < b < t_4$. There are four subsets of S : \emptyset , $\{a\}$, $\{b\}$, and $\{a, b\} = S$. Then

$$[t_1, t_2] \cap S = \emptyset, \quad [t_2, t_3] \cap S = \{a\}, \quad [t_3, t_4] \cap S = \{b\}, \quad [t_1, t_4] \cap S = S.$$

Hence, S is shattered by \mathcal{C} . This holds for every two-point set in \mathbb{R} , which proves (1). To prove (2), let $S = \{a, b, c\}$ be an arbitrary three-point set with $a < b < c$. Then the intersection of any $[t_1, t_2] \in \mathcal{C}$ with S containing a and c must necessarily contain b as well. This shows that no three-point set can be shattered by \mathcal{C} , so by Lemma 1 we conclude that $V(\mathcal{C}) = 2$.

Figure 1: Impossibility of shattering an affinely independent four-point set in \mathbb{R}^2 by closed halfspaces.

2.3 Closed halfspaces

Let $Z = \mathbb{R}^2$, and let \mathcal{C} consist of all closed halfspaces, i.e., sets of the form

$$\{z = (z_1, z_2) \in \mathbb{R}^2 : w_1 z_1 + w_2 z_2 \geq b\}$$

for all choices of $w_1, w_2, b \in \mathbb{R}$ such that $(w_1, w_2) \neq (0, 0)$. Then $V(\mathcal{C}) = 3$.

To see that $\mathbb{S}_3(\mathcal{C}) = 2^3 = 8$, it suffices to consider any set $S = \{z_1, z_2, z_3\}$ of three *non-collinear* points. Then it is not hard to see that for any $S' \subseteq S$ it is possible to choose a closed halfspace $C \in \mathcal{C}$ that would contain S' , but not S . To see that $\mathbb{S}_4(\mathcal{C}) < 2^4$, we must look at all four-point sets $S = \{z_1, z_2, z_3, z_4\}$. There are two cases to consider:

1. One point in S lies in the convex hull of the other three. Without loss of generality, let's suppose that $z_1 \in \text{conv}(S')$ with $S' = \{z_2, z_3, z_4\}$. Then there is no $C \in \mathcal{C}$ such that $C \cap S = S'$. The reason for this is that every $C \in \mathcal{C}$ is a convex set. Hence, if $S' \subset C$, then any point in $\text{conv}(S')$ is contained in C as well.
2. No point in S is in the convex hull of the remaining points. This case, when S is an *affinely independent set*, is shown in Figure 1. Let us partition S into two disjoint subsets, S_1 and S_2 , each consisting of "opposite" points. In the figure, $S_1 = \{z_1, z_3\}$ and $S_2 = \{z_2, z_4\}$. Then it is easy to see that there is no halfspace C whose boundary could separate S_1 from its complement S_2 . This is, in fact, the famous "XOR counterexample" of Minsky and Papert [MP69], which has demonstrated the impossibility of universal concept learning by one-layer perceptrons.

Since any four-point set in \mathbb{R}^2 falls under one of these two cases, we have shown that no such set can be shattered by \mathcal{C} . Hence, $V(\mathcal{C}) = 3$.

More generally, if $Z = \mathbb{R}^d$ and \mathcal{C} is the class of all closed halfspaces

$$\left\{ z \in \mathbb{R}^d : \sum_{j=1}^d w_j z_j \geq b \right\}$$

for all $w = (w_1, \dots, w_d) \in \mathbb{R}^d$ such that at least one of the w_j 's is nonzero and all $b \in \mathbb{R}$, then $V(\mathcal{C}) = d + 1$ [WD81]; we will see a proof of this fact shortly.

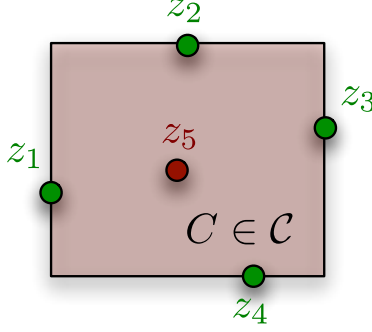

Figure 2: Impossibility of shattering a five-point set by axis-parallel rectangles.

2.4 Axis-parallel rectangles

Let $Z = \mathbb{R}^2$, and let \mathcal{C} consist of all “axis-parallel” rectangles, i.e., sets of the form $C = [a_1, b_1] \times [a_2, b_2]$ for all $a_1, b_1, a_2, b_2 \in \mathbb{R}$. Then $V(\mathcal{C}) = 4$.

First we exhibit a four-point set $S = \{z_1, z_2, z_3, z_4\}$ that is shattered by \mathcal{C} . It suffices to take $z_1 = (-1, -1)$, $z_2 = (-1, 1)$, $z_3 = (1, -1)$, $z_4 = (1, 1)$. To show that no five-point set is shattered by \mathcal{C} , consider an arbitrary $S = \{z_1, z_2, z_3, z_4, z_5\}$. Of these, pick any one point with the smallest first coordinate and any one point with the largest first coordinate, and likewise for the second coordinate (refer to Figure 2), for a total of at most four. Let S' denote the set consisting of these points; in Figure 2, $S' = \{z_1, z_2, z_3, z_4\}$. Then it is easy to see that any $C \in \mathcal{C}$ that contains the points in S' must contain all the points in $S \setminus S'$ as well. Hence, no five-point set in \mathbb{R}^2 can be shattered by \mathcal{C} , so $V(\mathcal{C}) = 5$.

The same argument also works for axis-parallel rectangles in \mathbb{R}^d , i.e., all sets of the form $C = [a_1, b_1] \times [a_2, b_2] \times \dots \times [a_d, b_d]$, leading to the conclusion that the VC dimension of the set of all axis-parallel rectangles in \mathbb{R}^d is equal to $2d$.

2.5 Sets determined by finite-dimensional function spaces

The following result is due to Dudley [Dud78]. Let Z be arbitrary, and let \mathcal{G} be an m -dimensional linear space of functions $g : Z \rightarrow \mathbb{R}$, which means that each $g \in \mathcal{G}$ has a unique representation of the form

$$g = \sum_{j=1}^m c_j \psi_j,$$

where $\psi_1, \dots, \psi_m : Z \rightarrow \mathbb{R}$ form a fixed linearly independent set and c_1, \dots, c_m are real coefficients. Consider the class

$$\mathcal{C} = \left\{ \{z \in Z : g(z) \geq 0\} : g \in \mathcal{G} \right\}.$$

Then $V(\mathcal{C}) \leq m$.

To prove this, we need to show that no set of $m+1$ points in Z can be shattered by \mathcal{C} . To that end, let us fix $m+1$ arbitrary points $z_1, \dots, z_{m+1} \in Z$ and consider the mapping $L : \mathcal{G} \rightarrow \mathbb{R}^{m+1}$ defined by

$$L(g) \triangleq (g(z_1), \dots, g(z_{m+1})).$$

It is easy to see that because \mathcal{G} is a linear space, L is a linear mapping, i.e., for any $g_1, g_2 \in \mathcal{G}$ and any $c_1, c_2 \in \mathbb{R}$ we have $L(c_1 g_1 + c_2 g_2) = c_1 L(g_1) + c_2 L(g_2)$. Since $\dim \mathcal{G} = m$, the image of \mathcal{G} under L , i.e., the set

$$L(\mathcal{G}) = \{(g(z_1), \dots, g(z_{m+1})) \in \mathbb{R}^{m+1} : g \in \mathcal{G}\},$$

is a linear subspace of \mathbb{R}^{m+1} of dimension at most m . This means that there exists some nonzero vector $v = (v_1, \dots, v_{m+1}) \in \mathbb{R}^{m+1}$ orthogonal to $L(\mathcal{G})$, i.e., for every $g \in \mathcal{G}$

$$v_1 g(z_1) + \dots + v_{m+1} g(z_{m+1}) = 0. \quad (3)$$

Without loss of generality, we may assume that at least one component of v is strictly negative (otherwise we can take $-v$ instead of v and still get (3)). Hence, we can rearrange the equality in (3) as

$$\sum_{i:v_i \geq 0} v_i g(z_i) = - \sum_{i:v_i < 0} v_i g(z_i), \quad \forall g \in \mathcal{G}. \quad (4)$$

Now let us suppose that $\mathbb{S}_{m+1}(\mathcal{C}) = 2^{m+1}$ and derive a contradiction. Consider a binary $(m+1)$ -tuple $b = (b_1, \dots, b_{m+1}) \in \{0, 1\}^{m+1}$, where $b_j = 1$ if and only if $v_j \geq 0$, and 0 otherwise. Since we assumed that $\mathbb{S}_{m+1}(\mathcal{C}) = 2^{m+1}$, there exists some $g \in \mathcal{G}$ such that

$$(\mathbf{1}_{\{g(z_1) \geq 0\}}, \dots, \mathbf{1}_{\{g(z_{m+1}) \geq 0\}}) = b.$$

By our definition of b , this means that the left-hand side of (4) is nonnegative, while the right-hand side is negative, which is a contradiction. Hence, $\mathbb{S}_{m+1}(\mathcal{C}) < 2^{m+1}$, so $V(\mathcal{C}) \leq m$.

This result can be used to bound the VC dimension of many classes of sets:

- Let \mathcal{C} be the class of all closed halfspaces in \mathbb{R}^d . Then any $C \in \mathcal{C}$ can be represented in the form $C = \{z : g(z) \geq 0\}$ for $g(z) = \langle w, z \rangle - b$ with some nonzero $w \in \mathbb{R}^d$ and $b \in \mathbb{R}$. The set \mathcal{G} of all such affine functions on \mathbb{R}^d is a linear space of dimension $d+1$, so by the above result we have $V(\mathcal{C}) \leq d+1$. In fact, we know that this holds with equality [WD81]. This can also be seen from the following result, due to Cover [Cov65]: Let \mathcal{G} be the linear space of functions spanned by functions ψ_1, \dots, ψ_m , and let $\{z_1, \dots, z_n\} \subset Z$ be such that the vectors $\Psi(z_i) = (\psi_1(z_i), \dots, \psi_m(z_i))$, $1 \leq i \leq n$, form a linearly independent set. Then for the class of sets $\mathcal{C} = \{\{z : g(z) \geq 0\} : z \in Z\}$ we have

$$|C \cap \{z_1, \dots, z_n\} : C \in \mathcal{C}| = \sum_{i=0}^{m-1} \binom{n-1}{i}.$$

The conditions needed for Cover's result are seen to hold for indicators of halfspaces, so letting $n = m = d+1$ we see that $\mathbb{S}_d(\mathcal{C}) = \sum_{i=0}^d \binom{d}{i} = 2^d$. Hence, $V(\mathcal{C}) = d+1$.

- Let \mathcal{C} be the class of all closed balls in \mathbb{R}^d , i.e., sets of the form

$$C = \left\{ z \in \mathbb{R}^d : \|z - x\|^2 \leq r^2 \right\}$$

where $x \in \mathbb{R}^d$ is the *center* of C and $r \in \mathbb{R}^+$ is its *radius*. Then we can write $C = \{z : g(z) \geq 0\}$, where

$$g(z) = r^2 - \|z - x\|^2 = r^2 - \sum_{j=1}^d |z_j - x_j|^2. \quad (5)$$

Expanding the second expression for g in (5), we get

$$g(z) = r^2 - \sum_{j=1}^d x_j^2 + 2 \sum_{j=1}^d x_j z_j - \sum_{j=1}^d z_j^2,$$

which can be written in the form $g(z) = \sum_{k=1}^{d+2} c_k \psi_k(z)$, where $\psi_1(z) = 1$, $\psi_k(z) = z_k$ for $k = 2, \dots, d+1$, and $\psi_{d+2} = \sum_{j=1}^d z_j^2$. It can be shown that the functions $\{\psi_k\}_{k=1}^{d+2}$ are linearly independent. Hence, $V(\mathcal{C}) \leq d+2$. This bound, however, is not tight; as shown by Dudley [Dud79], the class of closed balls in \mathbb{R}^d has VC dimension $d+1$.

2.6 VC dimension vs. number of parameters

Looking back at all these examples, one may get the impression that the VC dimension of a set of binary-valued functions is just the number of parameters. This is not the case. Consider the following one-parameter family of functions:

$$g_\theta(z) \triangleq \sin(\theta z), \quad \theta \in \mathbb{R}.$$

However, the class of sets

$$\mathcal{C} = \left\{ \{z \in \mathbb{R} : g_\theta(z) \geq 0\} : \theta \in \mathbb{R} \right\}$$

has infinite VC dimension. Indeed, for any n , any collection of numbers $z_1, \dots, z_n \in \mathbb{R}$, and any binary string $b \in \{0, 1\}^n$, one can always find some $\theta \in \mathbb{R}$ such that

$$\text{sgn}(\sin(\theta z_i)) = \begin{cases} +1, & \text{if } b_i = 1 \\ -1, & \text{if } b_i = 0 \end{cases}.$$

3 Growth of shatter coefficients: the Sauer–Shelah lemma

The importance of VC classes in learning theory arises from the fact that, as n tends to infinity, the fraction of subsets of any $\{z_1, \dots, z_n\} \subset Z$ that are shattered by a given VC class \mathcal{C} tends to zero. We will prove this fact in this section by deriving a sharp bound on the shatter coefficients $\mathfrak{S}_n(\mathcal{C})$ of a VC class \mathcal{C} . This bound have been (re)discovered at least three times, first in a weak form by Vapnik and Chervonenkis [VC71] in 1971, then independently and in different contexts by Sauer [Sau72] and Shelah [She72] in 1972. In strict accordance with Stigler’s law of eponymy¹, it is known in the statistical learning literature as the *Sauer–Shelah lemma*.

Before we state and prove this result, we will collect some preliminaries and set up some notation. Given integers $n, d \geq 1$, let

$$\phi(n, d) \triangleq \begin{cases} \sum_{i=0}^d \binom{n}{i}, & \text{if } n > d \\ 2^n, & \text{if } n \leq d \end{cases}$$

If we adopt the convention that $\binom{n}{i} = 0$ for $i > n$, we can write

$$\phi(n, d) = \sum_{i=0}^d \binom{n}{i}$$

for all $n, d \geq 1$. We will find the following recursive relation useful:

Lemma 2.

$$\phi(n, d) = \phi(n-1, d) + \phi(n-1, d-1).$$

Proof. We have

$$\binom{n-1}{i-1} + \binom{n-1}{i} = \frac{(n-1)!}{(i-1)!(n-i)!} + \frac{(n-1)!}{i!(n-i-1)!}.$$

¹“No scientific discovery is named after its original discoverer” (http://en.wikipedia.org/wiki/Stigler's_Law_of_Eponymy)

Multiplying both sides by $i!(n-i)!$, we obtain

$$i!(n-i)! \left[\binom{n-1}{i-1} + \binom{n-1}{i} \right] = i(n-1)! + (n-i)(n-1)! = n!$$

Hence,

$$\binom{n-1}{i-1} + \binom{n-1}{i} = \frac{n!}{i!(n-i)!} = \binom{n}{i}. \quad (6)$$

Using the definition of $\phi(n, d)$, as well as (6), we get

$$\phi(n, d) = \sum_{i=0}^d \binom{n}{i} = 1 + \sum_{i=1}^d \binom{n}{i} = 1 + \underbrace{\sum_{i=1}^d \binom{n-1}{i}}_{=\phi(n-1, d)} + \underbrace{\sum_{i=1}^d \binom{n-1}{i-1}}_{=\phi(n-1, d-1)}$$

and the lemma is proved. \square

Now for the actual result:

Theorem 1 (Sauer–Shelah lemma). *Let \mathcal{C} be a class of subsets of some space Z with $V(\mathcal{C}) = d < \infty$. Then for all n ,*

$$\mathbb{S}_n(\mathcal{C}) \leq \phi(n, d). \quad (7)$$

Proof. There are several different proofs in the literature; we will use an inductive argument following Blumer et al. [BEHW89].

We can assume, without loss of generality, that $n > d$, for otherwise $\mathbb{S}_n(\mathcal{C}) = 2^n = \phi(n, d)$. For an arbitrary finite set $S \subset Z$, let

$$\mathbb{S}(S, \mathcal{C}) \triangleq |\{S \cap C : C \in \mathcal{C}\}|,$$

where, as before, we count only the distinct sets of the form $S \cap C$. By definition, $\mathbb{S}_n(\mathcal{C}) = \sup_{S: |S|=n} \mathbb{S}(S, \mathcal{C})$. Thus, it suffices to prove the following: For any $S \subset Z$ with $|S| = n > d$, $\mathbb{S}(S, \mathcal{C}) \leq \phi(n, d)$.

For the purpose of computing $\mathbb{S}(S, \mathcal{C})$, any two $C_1, C_2 \in \mathcal{C}$ such that $S \cap C_1 = S \cap C_2$ are deemed equivalent. Hence, let

$$\mathcal{A} \triangleq \{A \subseteq S : A = S \cap C \text{ for some } C \in \mathcal{C}\}.$$

Then we may write

$$\mathbb{S}(S, \mathcal{C}) = |\{S \cap C : C \in \mathcal{C}\}| = |\{A \subseteq S : A = S \cap C \text{ for some } C \in \mathcal{C}\}| = |\mathcal{A}|.$$

Moreover, it is easy to see that $V(\mathcal{A}) \leq V(\mathcal{C}) = d$.

Thus, the desired result is equivalent to saying that if \mathcal{A} is a collection of subsets of an n -element set S (which we may, without loss of generality, take to be $[n] \triangleq \{1, \dots, n\}$) with $V(\mathcal{A}) \leq d < n$, then $|\mathcal{A}| \leq \phi(n, d)$. We will prove this statement by “double induction” on n and d . First of all, the statement (7) holds for all $n \geq 1$ and $d = 0$. Indeed, if $V(\mathcal{A}) = 0$, then $|\mathcal{A}| = 1 \leq 2^n$. Now assume that (7) holds for all n and all \mathcal{A} with $V(\mathcal{A}) \leq d-1$, and for all integers up to $n-1$ and all \mathcal{A} with $V(\mathcal{A}) \leq d$. Now let $S = [n]$, and let \mathcal{A} be a collection of subsets of $[n]$ with $V(\mathcal{A}) = d < n$. We will show that $|\mathcal{A}| \leq \phi(n, d)$.

To prove this claim, let us choose an arbitrary $i \in S$ and define

$$\begin{aligned}\mathcal{A} \setminus i &\triangleq \{A \setminus \{i\} : A \in \mathcal{A}\} \\ \mathcal{A}_i &\triangleq \{A \in \mathcal{A} : i \notin A, A \cup \{i\} \in \mathcal{A}\}\end{aligned}$$

Observe that both $\mathcal{A} \setminus i$ and \mathcal{A}_i are classes of subsets of $S \setminus \{i\}$. Moreover, since A and $A \cup \{i\}$ map to the same element of $\mathcal{A} \setminus i$, while $|\mathcal{A}_i|$ is the number of pairs of sets in \mathcal{A} that map into the same set in $\mathcal{A} \setminus i$, we have

$$|\mathcal{A}| = |\mathcal{A} \setminus i| + |\mathcal{A}_i|. \quad (8)$$

Since $\mathcal{A} \setminus i \subseteq \mathcal{A}$, we have $V(\mathcal{A} \setminus i) \leq V(\mathcal{A}) \leq d$. Also, every set in $\mathcal{A} \setminus i$ is a subset of $S \setminus \{i\}$, which has cardinality $n - 1$. Therefore, by the inductive hypothesis $|\mathcal{A} \setminus i| \leq \phi(n - 1, d)$. Next, we show that $V(\mathcal{A}_i) \leq d - 1$. Suppose, to the contrary, that $V(\mathcal{A}_i) = d$. Then there must exist some $T \subseteq S \setminus \{i\}$ with $|T| = d$ that is shattered by \mathcal{A}_i . But then $T \cup \{i\}$ is shattered by \mathcal{A} . To see this, given any $T' \subseteq T$ choose some $A \in \mathcal{A}_i$ such that $T \cap A = T'$ (this is possible since T is shattered by \mathcal{A}_i). But then $A \cup \{i\} \in \mathcal{A}$ (by definition of \mathcal{A}_i), and

$$(T \cup \{i\}) \cap (A \cup \{i\}) = (T \cap A) \cup \{i\} = T' \cup \{i\}.$$

Since this is possible for an arbitrary $T' \subseteq T$, we conclude that $T \cup \{i\}$ is shattered by \mathcal{A} . Now, since $T \subseteq S \setminus \{i\}$, we must have $i \notin T$, so $|T \cup \{i\}| = |T| + 1 = d + 1$, which means that there exists a $(d + 1)$ -element subset of $S = [n]$ that is shattered by \mathcal{A} . But this contradicts our assumption that $V(\mathcal{A}) \leq d$. Hence, $V(\mathcal{A}_i) \leq d - 1$. Since \mathcal{A}_i is a collection of subsets of $S \setminus \{i\}$, we must have $|\mathcal{A}_i| \leq \phi(n - 1, d - 1)$ by the inductive hypothesis. Hence, from (8) and from Lemma 2 we have

$$|\mathcal{A}| = |\mathcal{A} \setminus i| + |\mathcal{A}_i| \leq \phi(n - 1, d) + \phi(n - 1, d - 1) = \phi(n, d).$$

This completes the induction argument and proves (7). \square

Corollary 1. *If \mathcal{C} is a collection of sets with $V(\mathcal{C}) \leq d < \infty$, then*

$$\mathbb{S}_n(\mathcal{C}) \leq (n + 1)^d.$$

Moreover, if $n \geq d$, then

$$\mathbb{S}_n(\mathcal{C}) \leq \left(\frac{en}{d}\right)^d,$$

where e is the base of the natural logarithm.

Proof. For the first bound, write

$$\phi(n, d) = \sum_{i=0}^d \binom{n}{i} = \sum_{i=1}^d \frac{n!}{i!(n-i)!} \leq \sum_{i=1}^d \frac{n^i}{i!} \leq \sum_{i=0}^d \frac{n^i d!}{i!(d-i)!} = \sum_{i=0}^d n^i \binom{d}{i} = (n + 1)^d,$$

where the last step uses the binomial theorem. On the other hand, if $d/n \leq 1$, then

$$\left(\frac{d}{n}\right)^d \phi(n, d) = \left(\frac{d}{n}\right)^d \sum_{i=0}^d \binom{n}{i} \leq \sum_{i=1}^d \left(\frac{d}{n}\right)^i \binom{n}{i} \leq \sum_{i=1}^n \left(\frac{d}{n}\right)^i \binom{n}{i} = \left(1 + \frac{d}{n}\right)^n \leq e^d,$$

where we again used the binomial theorem. Dividing both sides by $(d/n)^d$, we get the second bound. \square

Let \mathcal{C} be a VC class of subsets of some space Z . From the above corollary we see that

$$\limsup_{n \rightarrow \infty} \frac{\mathbb{S}_n(\mathcal{C})}{2^n} \leq \lim_{n \rightarrow \infty} \frac{(n+1)^{V(\mathcal{C})}}{2^n} = 0.$$

In other words, as n becomes large, the fraction of subsets of an arbitrary n -element set $\{z_1, \dots, z_n\} \subset Z$ that are shattered by \mathcal{C} becomes negligible. Moreover, combining the bounds of the corollary with the Finite Class Lemma for Rademacher averages, we get the following:

Theorem 2. *Let \mathcal{F} be a VC class of binary-valued functions $f : Z \rightarrow \{0, 1\}$ on some space Z . Let Z^n be an i.i.d. sample of size n drawn according to an arbitrary probability distribution $P \in \mathcal{P}(Z)$. Then*

$$\mathbb{E}R_n(\mathcal{F}(Z^n)) \leq 2\sqrt{\frac{V(\mathcal{F}) \log(n+1)}{n}}.$$

A more refined *chaining technique* [Dud78] can be used to remove the logarithm in the above bound:

Theorem 3. *There exists an absolute constant $C > 0$, such that under the conditions of the preceding theorem*

$$\mathbb{E}R_n(\mathcal{F}(Z^n)) \leq C\sqrt{\frac{V(\mathcal{F})}{n}}.$$
